

Sandy decors

- rotate all cilia by constant angle

- add other cilia in random phase

$$T_{ij} (\varphi_i = \hat{\varphi}_i, \varphi_j = \hat{\varphi}_j, \varphi_k = \hat{\varphi} + k + i, j).$$

- add next-to-nearest neighbor interactions.

$$\text{start at } \varphi_1 + \dots + \varphi_N \equiv \sum c^{i\varphi_{k_1, k_2}} \pmod{2\pi}.$$

Model extensions

- other test patterns?

- cilia bundles?

- (Waveform compliance internal dissipation)

Multistability

- basins of attraction.
(Vo: L_p -adaptation)

Noise:

- Multiple isolated regions of stable states in reciprocal lattice
 \Rightarrow stochastic transitions.

Multistability

• test 1a (brute-force).

~~6x6~~

$N = 10$ cilia chain.

ensemble of $n = 100$. random initial cond.

propagate in time
for long time

decide which Φ^* is close.

• test 1b

6×6 cilia carpet.

• test 2. (flow-field), R^N . $\frac{10^{36}}{36}$ ↓

Results

- Multi-scale films with exp. beat pattern
- Poincaré maps

linear stability analysis
- eigenvalue spectrum

- 'Morin-Waggon' theorem
